Course Outlines

- **Chapter (1):** XML

  What is XML? What XML can do? How to write XML?

- **Chapter (2):** JSON

  What is JSON? What JSON can do? How to write JSON?

- **Chapter (3):** JSON APIs

 *Used to parse JSON using Java API*

Chapter 1

XML
What, Why & How?
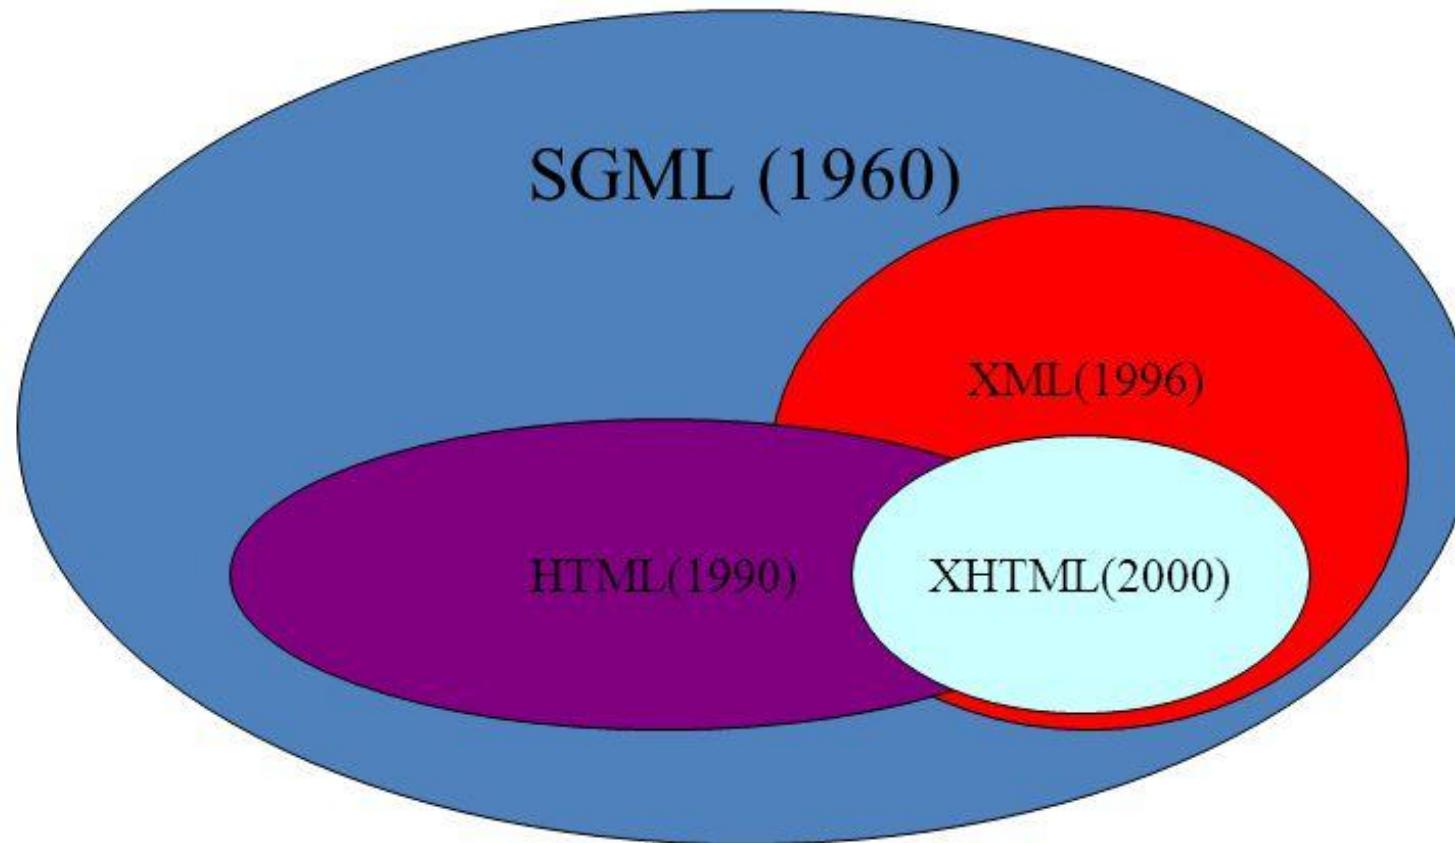

Ch1 : What is XML?

- Stands for e**X**tensible **M**arkup **L**anguage.

- XML is a markup language much like HTML used to describe data.

- W3C Recommendation, since February 1998.

- XML was designed to be both human- and machine-readable.

History: SGML vs. HTML vs. XML

http://www.w3.org/TR/2006/REC-xml-20060816/

Ch1 : XML Features

- XML is easy to understand.
- It is platform independent.
- XML was designed to **store** and **transport** data.
  - **Store Data**
    - XML Databases
      - XML-Enabled (Oracle, MS SQL Server, DB2, …)
      - Native-XML (BaseX, eXist, …)
    - User Interface Design (Qt, JavaFX, Android, …)
    - Configuration Files (Frameworks, Libraries, Mapping, …)
    - Settings Files(IDEs, Programs, Games, …)
  - **Transport Data**
    - Web Services (SOAP, REST, …)
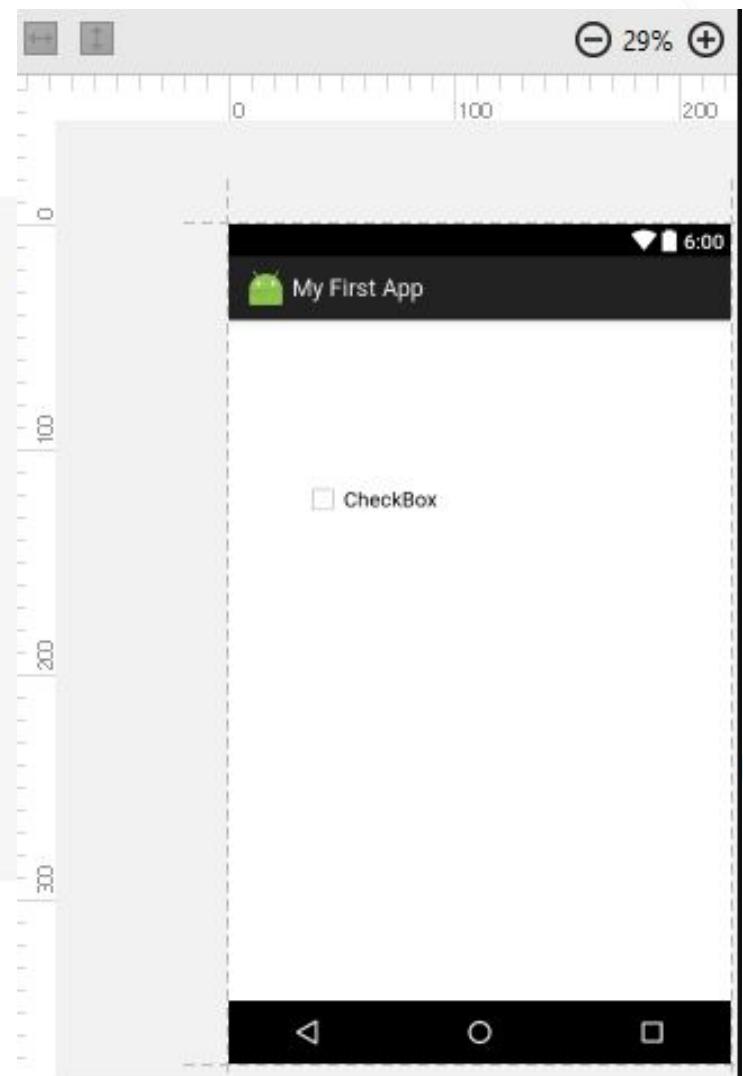

Ch1 : Why XML?

- **Android Views:**

`view_customs.xml` to be:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/custom_view"
    android:orientation="horizontal"
    android:layout_width="fill_parent"
    android:layout_height="wrap_content"
    >

    <TextView android:id="@+id/tv"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/app_name"
        />
</LinearLayout>
```

Ch1 : Why XML?

- **iOS Storyboard:**

Ch1 : Why XML?

- **Maven and POM.xml:**

android-maven-example / pom.xml

Code | Blame | 132 lines (118 loc) · 4.86 KB

```xml
12
13          <modules>
14              <module>androidexample-lib</module>
15              <module>androidexample-app</module>
16              <module>androidexample-tests</module>
17          </modules>
18
19
20      <dependencyManagement>
21          <dependencies>
22              <dependency>
23                  <groupId>com.google.android</groupId>
24                  <artifactId>android</artifactId>
25                  <version>4.1.1.4</version>
26                  <scope>provided</scope>
27              </dependency>
28
29              <dependency>
30                  <groupId>com.google.android</groupId>
31                  <artifactId>android-test</artifactId>
32                  <version>4.1.1.4</version>
33                  <scope>provided</scope>
34              </dependency>
35
36          </dependencies>
37      </dependencyManagement>
38
39      <build>
```

```
<?xml version="1.0" encoding="UTF-8"?>

<note>
```

Aya, Ahmed , Reminder , Don't …

```
    <to>Aya</to>
    <from>Ahmed</from>
    <heading>Reminder</heading>
    <body>Don't forget me this weekend!</body>
</note>
```

Ch1 : XML Does Not Do Anything

- Maybe it is a little hard to understand, but XML does not DO anything.

- The XML above is quite self-descriptive:
  - It has sender information.
  - It has receiver information
  - It has a heading
  - It has a message body.
  - But still, the XML above does not DO anything.
  - XML is just information wrapped in tags.

- Someone must write a piece of software
 to **send**, **receive**, **store**, or **display** it.

Ch1 : Self-Describing Syntax

- A prolog defines the XML version and the character encoding

```
<?xml version="1.0" encoding="UTF-8"?>
```

- The next line is the root element of the document

```
<bookstore>
```

- The next line starts a <book> element
  - The <book> elements have 4 child elements:
    <title>, <author>, <year>, <price>

```
<book category="web">
    <title lang="en">Learning XML</title>
    <author>Erik T. Ray</author>
        <year>2003</year>
        <price>39.95</price>
```

- The next line ends the book element

```
</book>
```
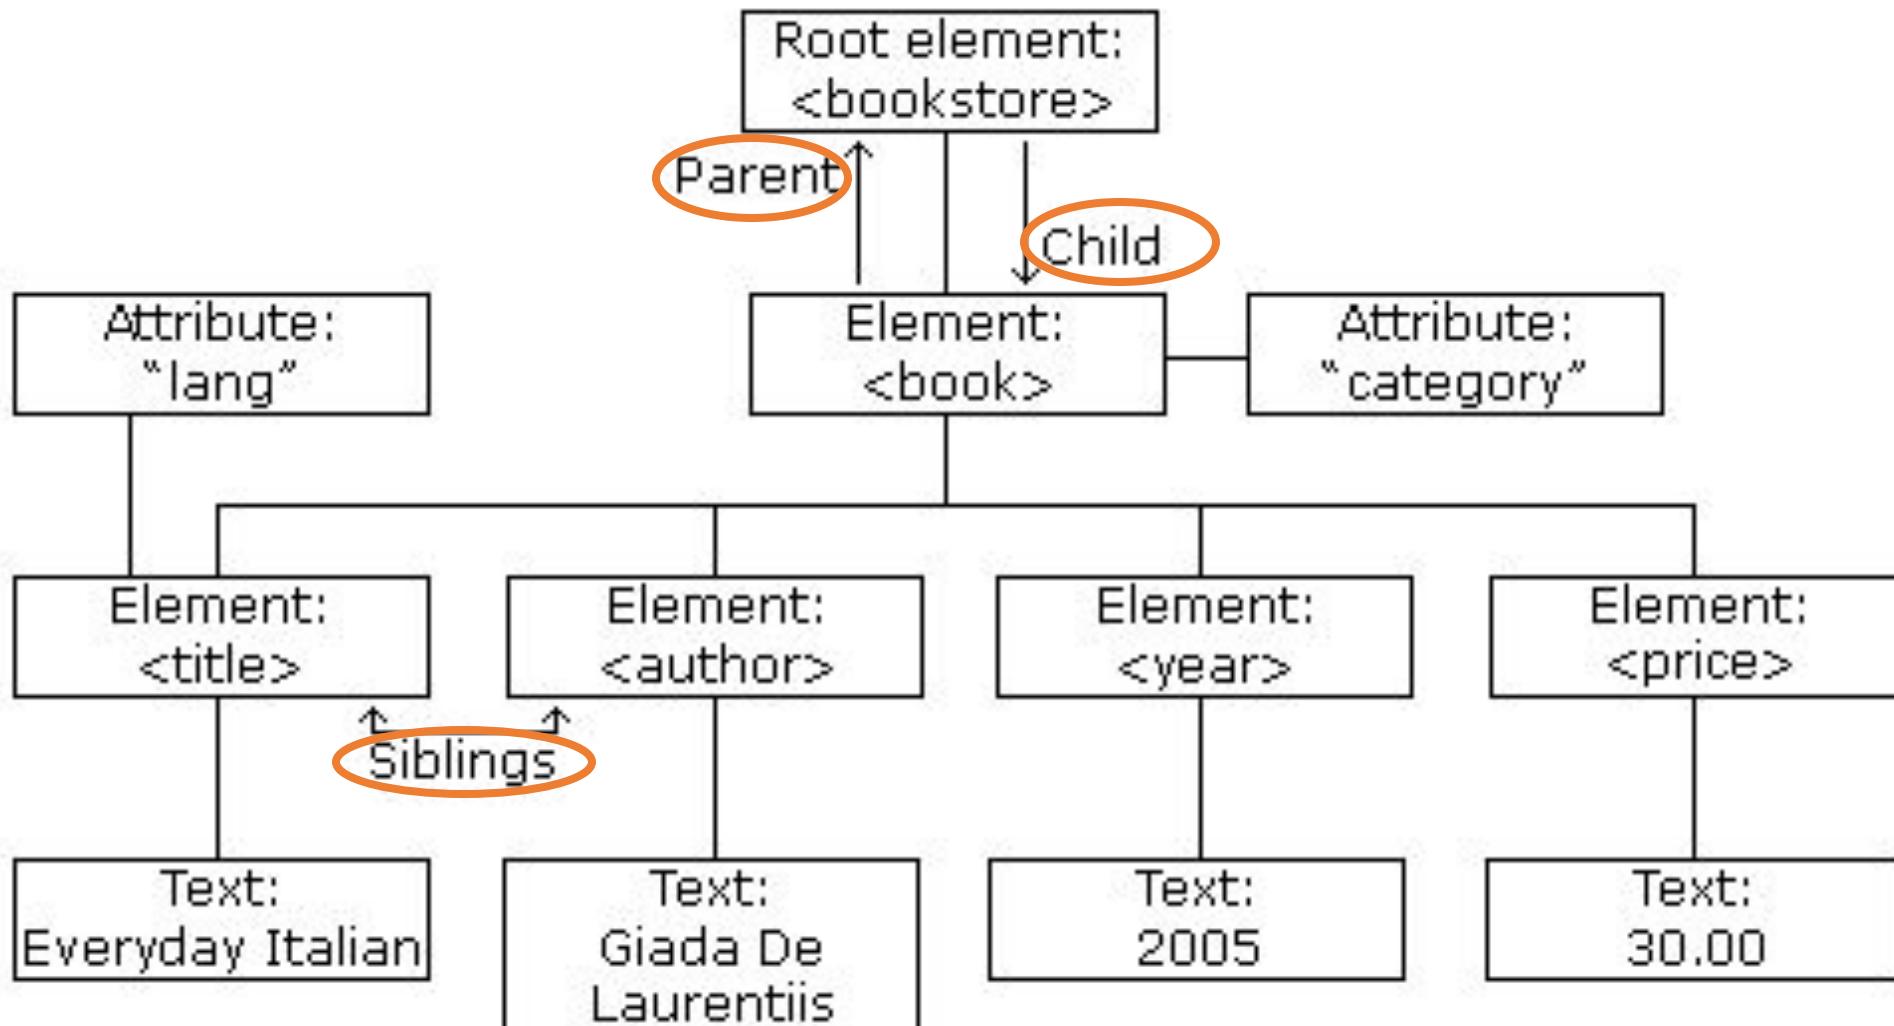

- The next line ends the root element of the document

```
</bookstore>
```

Ch1 : XML Tree

Ch1 : XML Tree

- XML documents form a tree structure that starts at "the root" and branches to "the leaves".

- XML documents are formed as element trees.

- An XML tree starts at a root element and branches from the root to child elements.

- All elements can have sub elements (child elements):

```
<root>
  <child>
    <subchild>.....</subchild>
  </child>
</root>
```

- The terms **parent**, **child**, and **sibling** are used to describe the relationships between elements.

- Parents have children. Children have parents.

- Siblings are children on the same level (brothers and sisters).

- All elements can have text content and attributes.

Ch1 : XML Syntax Rules

XML Documents Must Have a Root Element

The XML Prolog
`<?xml version="1.0" encoding="UTF-8"?>`

All XML Elements Must Have a Closing Tag

XML Tags are Case Sensitive

XML Elements Must be Properly Nested

XML Attribute Values Must Always be Quoted

Ch1 : XML Syntax Rules

Entity References

CDATA Sections

Comments in XML

White-space is Preserved in XML

Well Formed XML

Java™ Education and Technology Services

Ch1 : XML Documents Must Have a Root Element

- XML documents **must** contain **one root** element that is the parent of all other elements:

```xml
<root>
  <child>
    <subchild>.....</subchild>
  </child>
</root>
```

- In this example <note> is the root element:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<note>
  <to>Aya</to>
  <from>Amin</from>
  <heading>Reminder</heading>
  <body>Don't forget me this weekend!</body>
</note>
```

Ch1 : The XML Declaration (Prolog)

- This line is called the XML prolog:

```
<?xml version="1.0" encoding="UTF-8"?>
```

- The XML prolog is optional. If it exists, it must come first in the document.
- XML documents can contain international characters, like Norwegian øæå or French êèé.
- To avoid errors, you should specify the encoding used, or save your XML files as UTF-8.
- UTF-8 is the default character encoding for XML documents.

- UTF-8 is also the default encoding for HTML5, CSS, JavaScript, PHP, and SQL.

Ch1 : The XML Declaration (Prolog)

- This line is called the XML prolog:

```
<?xml version="1.0" encoding="UTF-8"?>   <
```

- The XML prolog is optional. If it exists, it must come first in the document.
- XML documents can contain international characters, like Norwegian øæå or French êèé.
- To avoid errors, you should specify the encoding used, or save your XML files as UTF-8.
- UTF-8 is the default character encoding for XML documents.

- UTF-8 is also the default encoding for HTML5, CSS, JavaScript, PHP, and SQL.

Ch1 : Syntax Rules for XML Declaration (Prolog)

- If the XML declaration is included, it must contain version number attribute.

- The Parameter names and values are case-sensitive.

- The names are always in lower case.

- The order of placing the parameters is important.
  The correct order is: version, encoding and standalone.

- Either single or double quotes may be used.

- The XML declaration has no closing tag i.e. </?xml>

Ch1 : XML declaration

```
<?xml version = "1.0" encoding = "UTF-8" standalone = "no" ?>
```

Parameter	Parameter_value	Parameter_description
Version	**1.0** or **1.1**	Specifies the version of the XML standard used. *(The Only Mandatory Part)*
Encoding	**UTF-8**, UTF-16, ISO-8859-1, Windows-1251, …	It defines the character encoding used in the document. *UTF-8 is the default encoding used.*
Standalone	**yes** or **no**	It informs the parser whether the document relies on the information from an external source, such as external document type definition (DTD), for its content. *The default value is set to no.* Setting it to yes tells the processor there are no external declarations required for parsing the document.

Ch1 : All XML Elements Must Have a Closing Tag

- In XML, it is illegal to omit the closing tag. All elements must have a closing tag:

```
<paragraph>This is a paragraph.</paragraph>

<line-break />
```

self closing tag for nobody elements

- Note: The XML prolog does not have a closing tag! This is not an error.
- The prolog is not a part of the XML document.

Ch1 : XML Tags are Case Sensitive

- XML tags are case sensitive.
- The tag \<Letter\> is different from the tag \<letter\>.
- Opening and closing tags must be written with the same case:

```
<message>This is correct</message>

<Message>This is NOT correct</message>
```

- "**Opening** and **Closing** tags" are often referred to as "**Start** and **End** tags".
- Use whatever you prefer.
- It is exactly the same thing.

Ch1 : XML Elements Must be Properly Nested

- In HTML, you might see ***improperly nested*** elements:

  `<b> <i> This text is bold and italic </b> </i>`

- In XML, all elements ***must be*** ***properly nested*** within each other:

  `<b> <i> This text is bold and italic </i> </b>`

- In the example above, "Properly nested" simply means that since the <i> element is opened inside the <b> element, it must be closed inside the <b> element.

Ch1 : XML Attribute Values Must Always be Quoted

- XML elements can have attributes in name/value pairs just like in HTML.
- In XML, the attribute values must always be quoted:

```
<note date="12/11/2020">
  <to>Aya</to>
  <from>Amin</from>
</note>

<note date='12/11/2020'>
  <to>Aya</to>
  <from>Amin</from>
</note>
```

Ch1 : Entity References

- Some characters have a special meaning in XML.

- If you place a character like "<" inside an XML element, it will generate an error because the parser interprets it as the start of a new element.

- This will generate an XML *error*:

```
<message>salary < 1000</message>
```

- To avoid this error, replace the "<" character with an entity reference:

```
<message>salary &lt; 1000</message>
```

- Entity References: Begin with ampersand (&) and end with semicolon (;)

Ch1 : Entity References

• There are 5 pre-defined entity references in XML:

<	<	less than
>	>	greater than
&	&	ampersand
'	'	apostrophe
"	"	quotation mark

• Only < and & are strictly illegal in XML, but it is a good habit to replace > with > as well.

Ch1 : CDATA Sections

- May contain text, reserved characters and white space
  - Reserved characters need not be replaced by entity references

- Not processed by XML parser

- Commonly used for scripting code (e.g., JavaScript)

- Begin with   :   `<![CDATA[`

- Terminate with   :   `]]>`

Ch1 : CDATA Example

```xml
1  <?xml version = "1.0"?>
2
3  <!-- Fig. 5.7 : cdata.xml                    -->
4  <!-- CDATA section containing C++ code      -->
5
6  <book title = "C++ How to Program" edition = "3">
7
8      <sample>
9              // C++ comment
10             if ( this->getX() &lt; 5 &amp;&amp; value[ 0 ] != 3 )
11                 cerr &lt;&lt; this->displayError();
12     </sample>
13
14     <sample>
15       <![CDATA[
16
17             // C++ comment
18             if ( this->getX() < 5 && value[ 0 ] != 3 )
19                 cerr << this->displayError();
20       ]]>
21     </sample>
22
23     C++ How to Program by Deitel &amp; Deitel
24 </book>
```

Entity references required if not in **CDATA** section

XML does not process **CDATA** section

Note the simplicity offered by **CDATA** section

- The syntax for writing comments in XML is similar to that of HTML:

  ```
  <!-- This is a comment -->
  ```

- Two dashes in the middle of a comment are not allowed:

  ```
  <!-- This is an invalid -- comment -->
  ```

Ch1 : White-space is Preserved in XML

- XML does not truncate multiple white-spaces
  (HTML truncates multiple white-spaces to one single white-space):

XML:	Hello Aya
HTML:	Hello Aya

- Windows applications store a new line as: carriage return and line feed (CR+LF).
- Unix and Mac OSX use LF./n
- Old Mac systems use CR./r

- **XML** stores a new line as **LF**.

XML document Considered ***well formed*** if it has:

1. Single root element.
2. Each element has start tag and end tag.
    - Empty element is defined as:
3. Tags well nested.
    - Incorrect: **<x><y>hello</x></y>**
    - Correct: **<x><y>hello</y></x>**
4. Attribute values in quotes(single or double).
5. Tag & Attributes names written as variable names:
    - Start with character,
    - One word "must not contain spaces", <first_name id='1' id='lang'>
    - Case sensitive.
6. An element may not have two attributes with the same name.
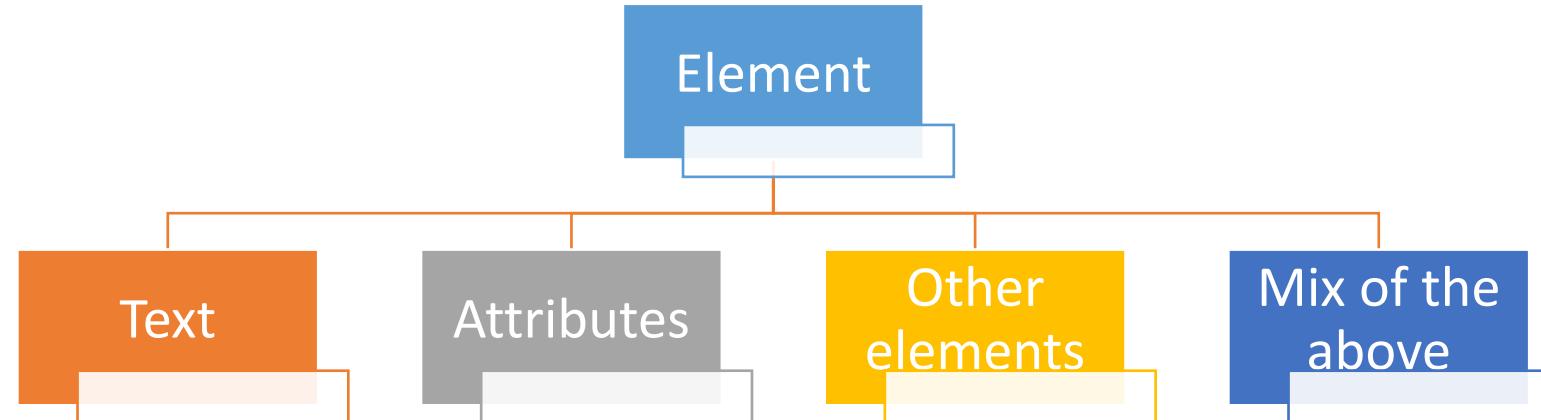

Ch1 : XML Elements

- What is an XML Element?
- Empty XML Elements
- XML Naming Rules
- Best Naming Practices
- Naming Styles
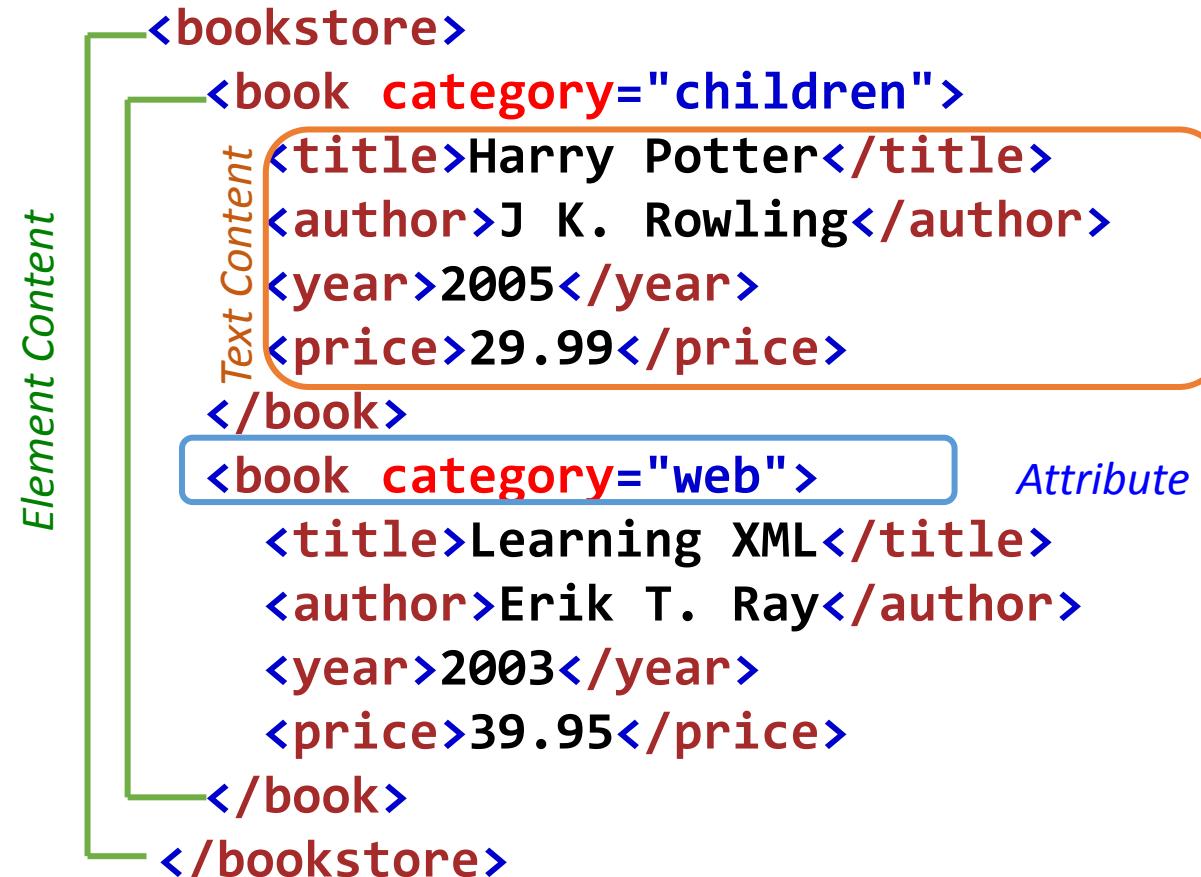

Ch1 : What is an XML Element?

- An XML document contains XML Elements.
- An XML element is everything from (including) the element's start tag to (including) the element's end tag.

```
<price id='1'>29.99</price>
```

Element

Text | Attributes | Other elements | Mix of the above

Ch1 : What is an XML Element?

```xml
<bookstore>
  <book category="children">
    <title>Harry Potter</title>
    <author>J K. Rowling</author>
    <year>2005</year>
    <price>29.99</price>
  </book>
  <book category="web">
    <title>Learning XML</title>
    <author>Erik T. Ray</author>
    <year>2003</year>
    <price>39.95</price>
  </book>
</bookstore>
```

Element Content

Text Content

Attribute

- In this example:

- <title>, <author>, <year>, and <price> have **text content** because they contain text (like 29.99).

- <bookstore> and <book> have **element contents**, because they contain elements.

- <book> has an **attribute** (category="children").

Ch1 : Empty XML Elements

- An element with no content is said to be empty.

- Empty elements can have attributes.

(Self-Closing)

- The two forms produce identical results in XML software (Readers, Parsers, Browsers).

- XML elements must follow these naming rules:
  - **Element names**

are case-sensitive

must start with a letter or underscore

can contain letters, digits, hyphens - , underscores, and periods . <first.name> <first_name> <first-name> <f12>

cannot start with the letters xml (or XML, or Xml, etc) <xmal>

cannot contain spaces

Ch1 : Best Naming Practices

- Create descriptive names, like this: <person>, <firstname>, <lastname>.

- Create short and simple names,
  like this: <book_title> not like this: <the_title_of_the_book>.

- Avoid "-" If you name something "first-name", <first_name>
  some software may think you want to subtract "name" from "first".

- Avoid "." If you name something "first.name", <first_name>
  some software may think that "name" is a property of the object "first".

- Avoid ":" Colons are reserved for namespaces (more later).

- Non-English letters like éòá are perfectly legal in XML,
  but watch out for problems if your software doesn't support them.

- There are no naming styles defined for XML elements. But here are some commonly used:

Style	Example	Description
Lower case	<firstname>	All letters lower case
Upper case	<FIRSTNAME>	All letters upper case
Underscore	<first_name>	Underscore separates words
Pascal case	<FirstName>	Uppercase first letter in each word
Camel case	<firstName>	Uppercase first letter in each word except the first

- If you choose a naming style, it is good to be consistent!
- XML documents often have a corresponding database.
- A common practice is to use the naming rules of the database for the XML elements.
- Camel case is a common naming rule in Java, JavaScript.

Ch1 : XML Attributes

- XML Attributes Must be Quoted
- XML Elements vs. Attributes
- My Favorite Way
- Avoid XML Attributes?
- XML Attributes for Metadata

Ch1 : XML Attributes Must be Quoted

- XML elements can have attributes, just like HTML.

- Attributes are designed to contain data related to a specific element.

- Attribute values must always be quoted. Either single or double quotes can be

  used.

- For a person's gender, the <person> element can be written like this:

- or like this:

```
<person gender="female">
```

- If the attribute value itself contains double quotes you can use single quotes, like this:

```
<person gender='female'>
```

- or you can use character entities:

```
<gangster name='George "Shotgun" Ziegler'>
```

```
<gangster name="George &quot;Shotgun&quot; Ziegler">
```

Ch1 : XML Elements vs. Attributes

- Take a look at these examples:

```
<person gender="female">
  <firstname>Aya</firstname>
  <lastname>Amin</lastname>
</person>
```

```
<person>
  <gender>female</gender>
  <firstname>Aya</firstname>
  <lastname>Amin</lastname>
</person>
```

- In the first example gender is an attribute.

- In the last, gender is an element. Both examples provide the same information.

- There are no rules about when to use attributes or when to use elements in XML.

Ch1 : How we do it:

- The following three XML documents contain exactly the same information:

- A date attribute is used in the first example:

- A <date> element is used in the second example:

- **An expanded <date> element is used in the third example (*Preferred*):**

```xml
<note date="2020-12-30">
  <to>Aya</to>
  <from>Amin</from>
</note>
```

```xml
<note>
  <date>2020-12-30</date>
  <to>Aya</to>
  <from>Amin</from>
</note>
```

```xml
<note>
  <date>
    <year>2020</year>
    <month>12</month>
    <day>30</day>
  </date>
  <to>Aya</to>
  <from>Amin</from>
</note>
```

Ch1 : Avoid XML Attributes?

- Some things to consider when using attributes are:

  ✔attributes cannot contain multiple values (elements can)
  ✔attributes cannot contain tree structures (elements can)
  ✔attributes are not easily expandable (for future changes)

- **Don't** end up like this:

```
<book>
<note day="30" month="12" year="2020"
to="Aya" from="Amin" heading="Reminder"
body="Don't forget me this weekend!">
</note>
```

Ch1 : XML Attributes for Metadata

- Sometimes ID references are assigned to elements.
- These IDs can be used to identify XML elements in much the same way as the id attribute in HTML.
- This example demonstrates this:

- The id attributes above are for identifying the different notes. It is not a part of the note itself.
- **What I'm trying to say here is that metadata (data about data) should be stored as attributes, and the data itself should be stored as elements.**

```xml
<messages>

<note id="501">
  <to>Aya</to>
  <from>Amin</from>
  <heading>Reminder</heading>
  <body>Don't forget me this weekend!</body>
</note>

<note id="502">
  <to>Aya</to>
  <from>Amin</from>
  <heading>Re: Reminder</heading>
  <body>I will not</body>
</note>

</messages>
```

Ch1 : XML Parser

- XML parser is a software, library or a package that provides interface for client applications to work with XML documents.
- It checks for proper format of the XML document and may also validate the XML documents.

- XML Parser: employees.xml
  - Processes XML document
  - Reads XML document
  - Checks syntax
  - Reports errors (if any)

- Example:
  - Internet browsers (Chrome, Firefox, Edge, Internet Explorer, …)
  - XML Editors (XmlSpy, Microsoft XML Notepad, XMLQuire, OxygenXML, …)
  - Built-in components in the Java JDK and several 3rd Party Libraries

Ch1 : XML Processing Instructions

- Processing instructions (PIs) allow documents to contain instructions for applications.
- PIs are not part of the character data of the document
  but MUST be passed through to the application.

- Processing instructions (PIs) can be used to pass information to applications.
- PIs can appear anywhere in the document outside the markup.
- They can appear in the prolog, including the document type definition (DTD),
  in textual content, or after the document.

- A PI starts with a special tag **<?** and ends with **?>**.
- Processing of the contents ends immediately after the string **?>** is encountered.

- Syntax: **<?**target instructions**?>**

Lab Exercise

- **1ˢᵗ Assignment: A Configuration File**

  - Design a configuration file for a library.

    - Info. of library consists of a location, a description of the library, a librarian and a lot of books.
    - Each book has title, ISBN, and Author.
    - The book contains also a preface and many of parts.
    - Each part has title and contains many of chapters.
    - Each chapter has title and contains a summary and many of sections.
    - Sections contain the content of the book as paragraphs.

> XML must have elements (usual and empty), attributes, and CDATA section

JSON

Introduction to JSON

- Stands for **J**ava **S**cript **O**bject **N**otation

- What is JSON?
  - JSON is a syntax for storing and exchanging text information.
  - JSON is lightweight text-data interchange format
  - JSON is language independent.

- JSON is smaller than XML, and faster and easier to parse.

Introduction to JSON

- JSON Files:
  - The filename extension is **".json"**
  - JSON Internet Media type is **"application/json"**

- All modern programming languages support JSON.

JSON vs XML

- Much Like XML:
  - JSON is plain text
  - JSON is "self-describing" (human readable)
  - JSON is hierarchical (values within values)
  - JSON can be parsed by JavaScript
  - JSON data can be transported using AJAX

- Much Unlike XML:
  - No end tag
  - Shorter
  - Quicker to read and write
  - Can be parsed using built-in JavaScript eval()
  - Uses arrays
  - No reserved words

Why JSON?

- For AJAX applications, JSON is faster & easier than XML:

- Using XML
  - Fetch an XML document
  - Use the XML DOM to loop through the document
  - Extract values and store in variables

- Using JSON
  - Fetch a JSON string
  - eval() the JSON string
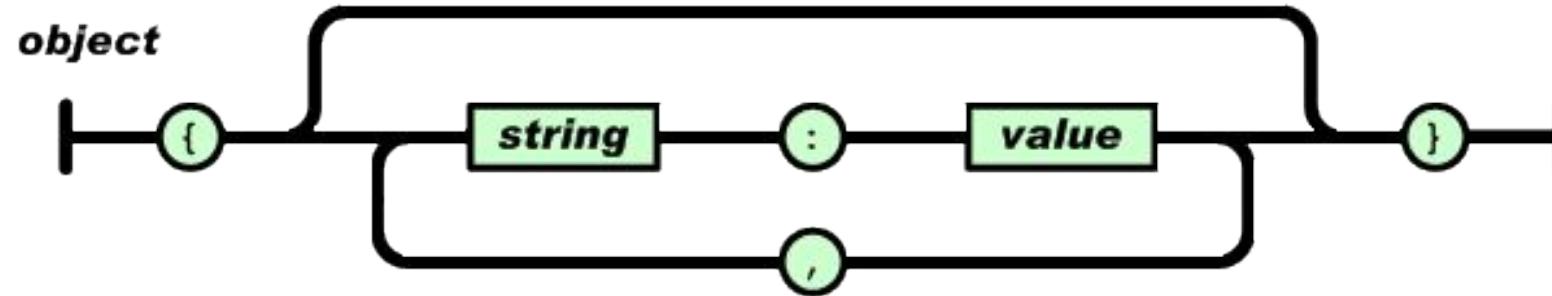

Example

```json
{
    "book": [
    {
        "id":100,
        "language":"Java",
        "edition":"third",
        "author":"Herbert Schildt"
    },
    {
        "id":200,
        "language":"C++",
        "edition":"second",
        "author":"E.Balagurusamy"
    }]
}
```

JSON Structure

- **JSON is built on two structures:**

  - ***A collection of name/value pairs.***
    - Like an *object*, record, struct, dictionary, hash table.

  - ***An ordered list of values.***
    - Like an *array*, vector, list, or sequence.

Object
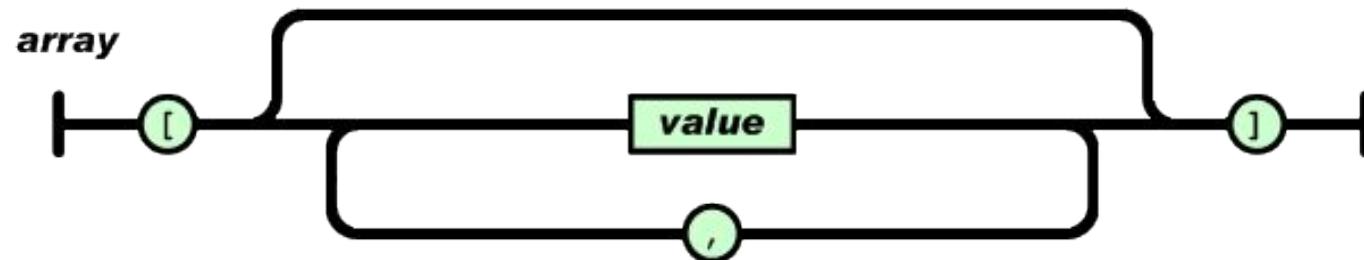

- An ***object***
  - is an unordered set of name/value pairs.
  - An object begins with **{** and ends with **}**
  - Each name is followed by **:** and the name/value pairs are separated by **,**

- Example:

  { "firstName":"Ahmed" , "lastName":"Omar" }

Array

- **An *array***
  - is an ordered collection of values.
  - An array begins with **[** and ends with **]**
  - Values are separated by **,**

- **Example:**

```
{
  "employees": [
    {"firstName":"John","lastName":"Doe"},
    {"firstName":"Anna","lastName":"Smith"},
    {"firstName":"Peter","lastName":"Jones"}
  ]
}
```

Value

- A **value** can be
  - a *string* in double quotes,
  - a *number*,
  - true or false
  - null,
  - an *object*
  - an *array*
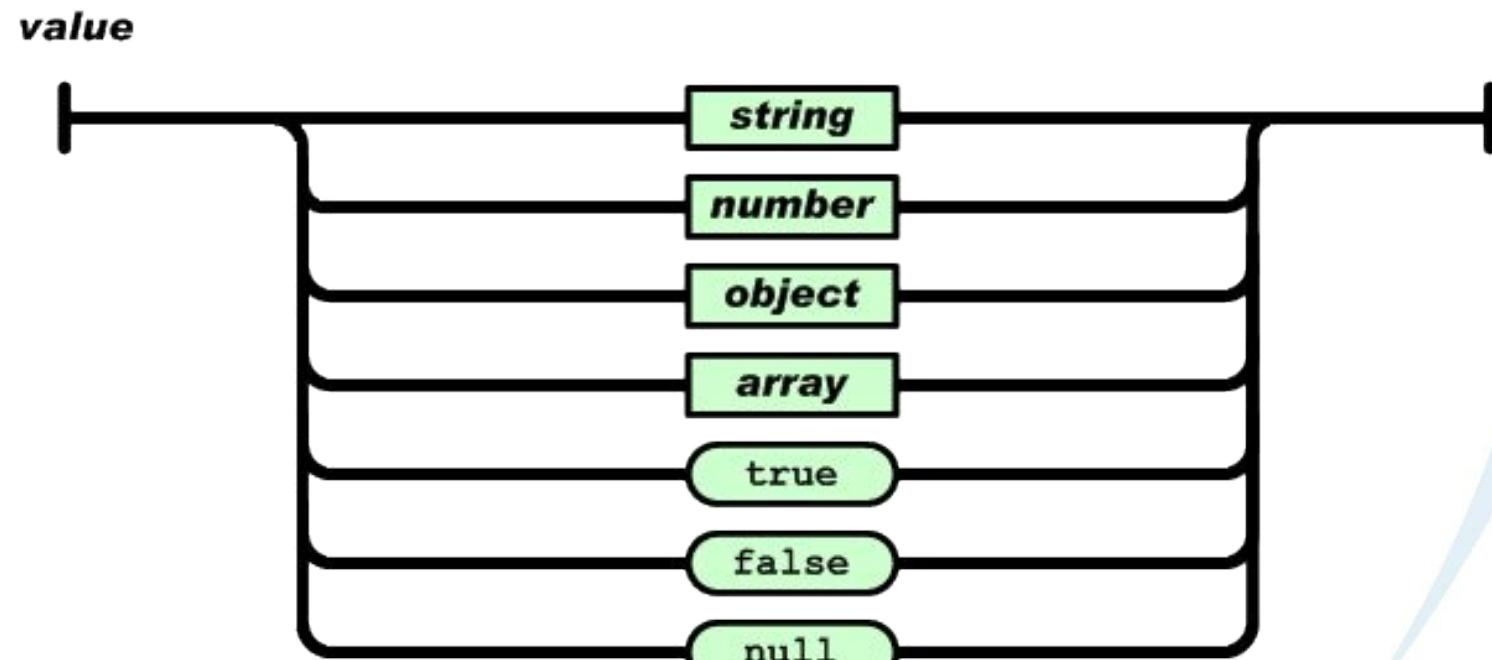

`name:"Amin"`   `id:100`

`flag:true`   `MyVar:null`
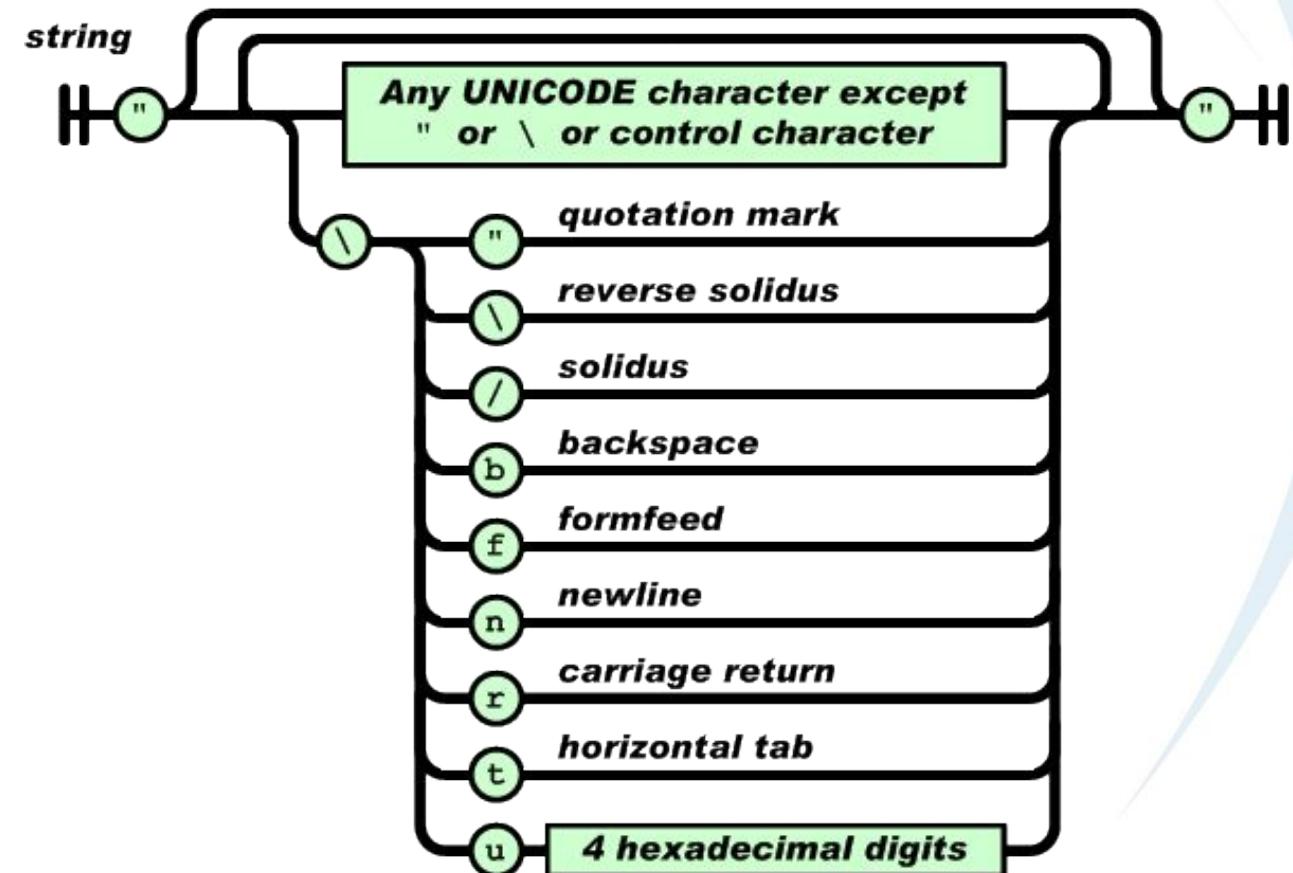

`{"id":1,"x":"y"}`

`"Students":[...,...]`
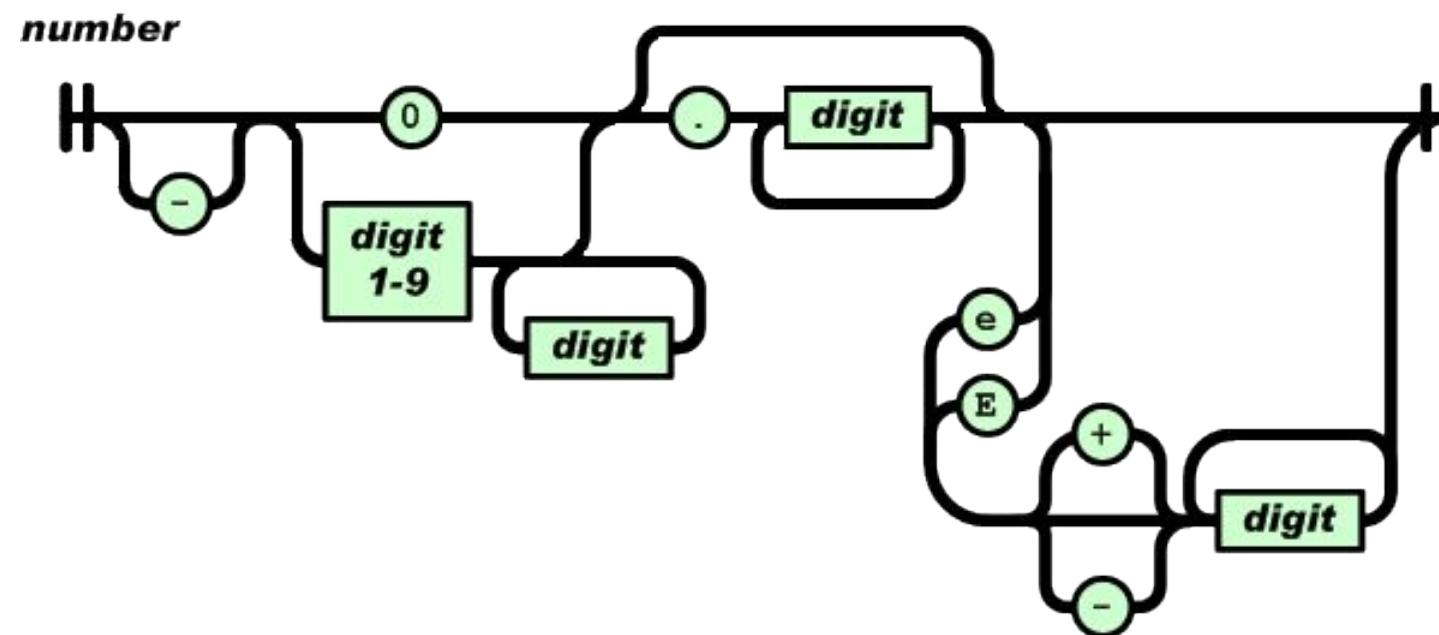

String

- A **string** is
  - Very much like a C or Java string.

  - A sequence of zero or more Unicode characters, wrapped in double quotes, using backslash escapes.

  - A character is represented as a single character string.

Number

- A **number** is
  - Very much like a C or Java number.
  - Except that the octal and hexadecimal formats are not used.

JSON Technologies

- JSON started unlike XML without any Validation Rules

- After the widespread usage of JSON,
  new Technologies emerged related to JSON similar to XML Technologies.

- **JSON Schema**: to validate JSON Documents

- **JSON Pointer**: to navigate and fetch data from JSON Documents

- And new JSON Technologies are still emerging

- Both XML and JSON are widely Adopted Data Exchange Formats

Assignment: A Configuration File

- Design a configuration file for a library.
  - Info. of library consists of a location, a description of the library, a librarian and a lot of books.
  - Each book has title, ISBN, and Author.
  - The book contains also a preface and many of parts.
  - Each part has title and contains many of chapters.
  - Each chapter has title and contains a summary and many of sections.
  - Sections contain the content of the book as paragraphs.
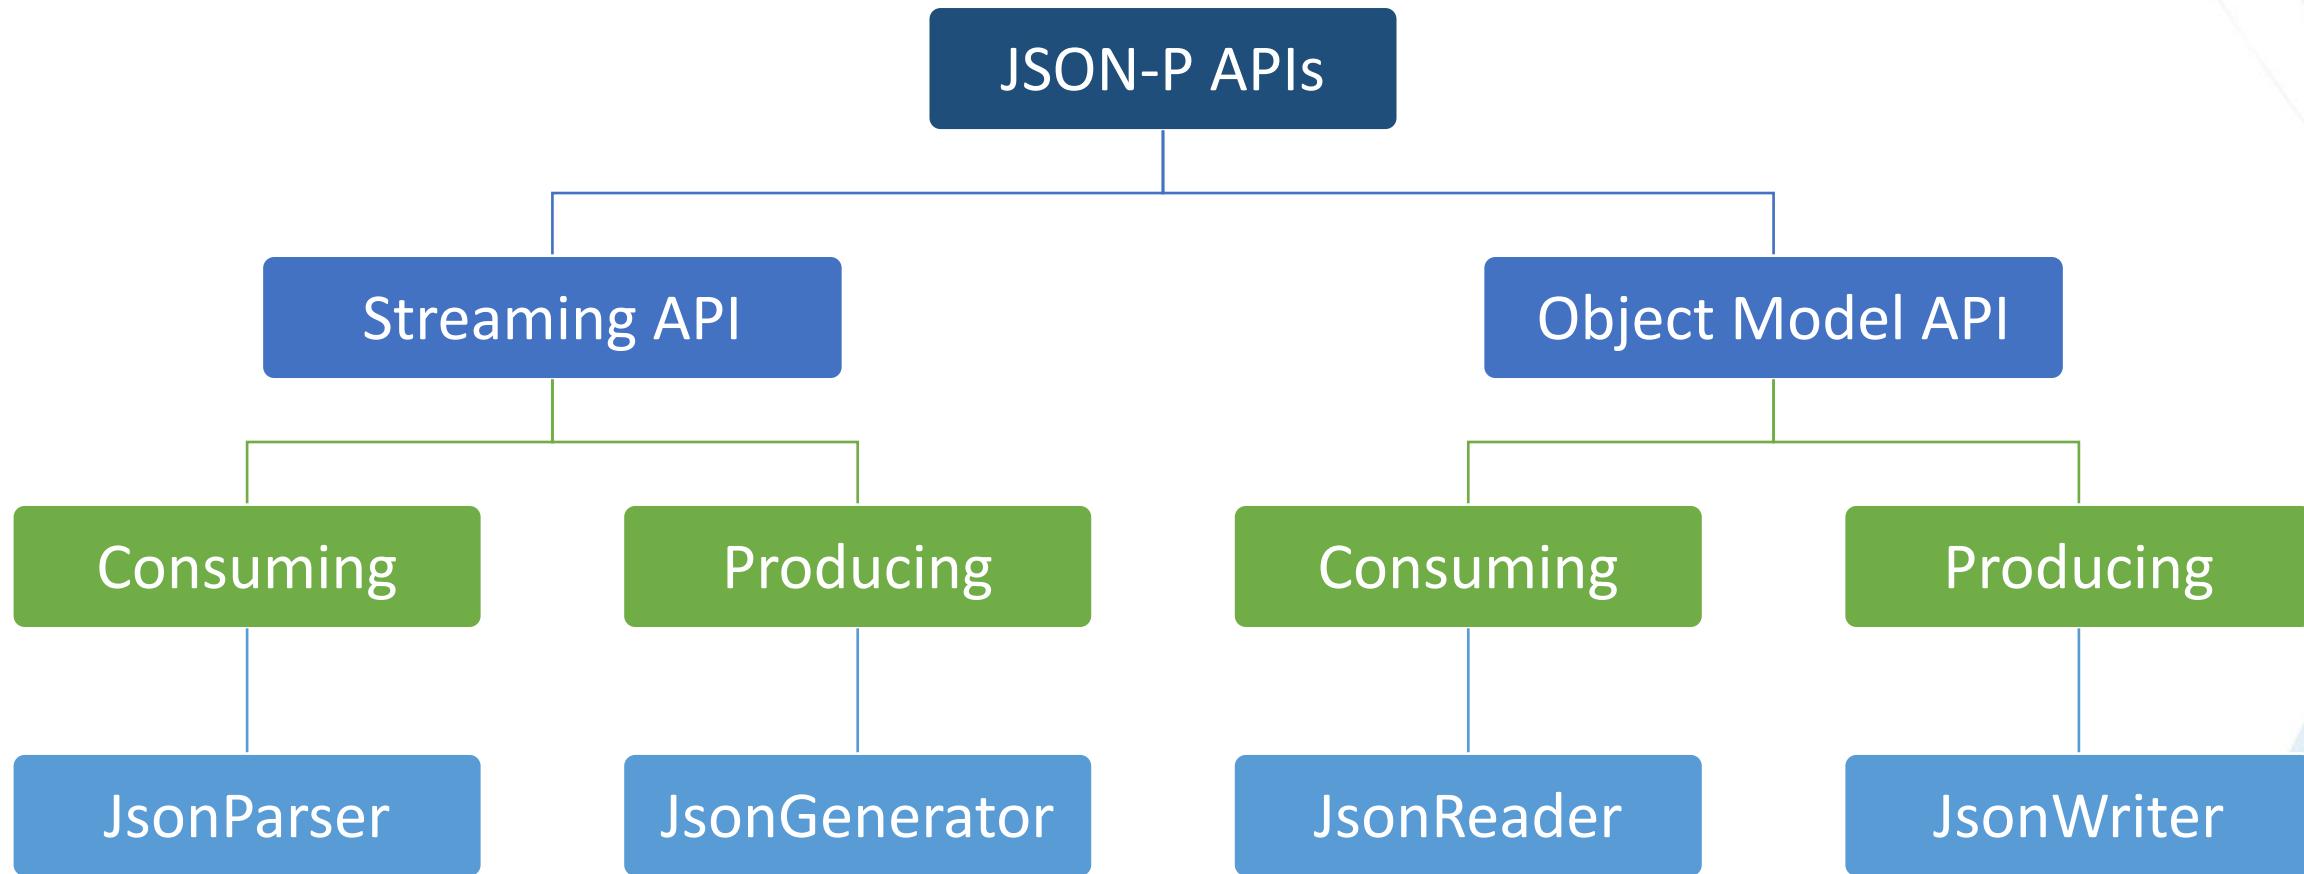

JSON-P

JSON Processing

- Java API for JSON Processing
  - JSON-P V1.0 JEE7: JSR 353 Specification
  - JSON-P V1.1 JEE8: JSR 374 Specification

- The goals of the API are to:
  - Produce/Consume JSON text in a *streaming* fashion (like StAX API for XML)
  - Build a Java *Object Model* for JSON text (like DOM API for XML)

Summary JSON-Binding JSON-Processing

JSON-P APIs

Streaming API

Object Model API

JSON Processing (Maven Dependencies)

```
<dependency>
    <groupId> javax.json </groupId>
    <artifactId> javax.json-api </artifactId>
    <version> 1.1.4 </version>
</dependency>
```

JSON-P API

```
<dependency>
    <groupId> org.glassfish </groupId>
    <artifactId> javax.json </artifactId>
    <version> 1.1.4 </version>
</dependency>
```

JSON-P Implementation

If running on a Server, you'd change the implementations dependencies scope to provided

JSON-P

Streaming API

Streaming API

- The Streaming API provides a way to parse and generate JSON text in a streaming fashion (a low-level API).

- The API provides an event-based parser and allows an application developer to ask for the next event (i.e., pull the event), rather than handling the event in a callback.

- The streaming model is adequate for local processing where only specific parts of the JSON structure need to be accessed, and random access to other parts of the data is not required.

- Parser events can be processed or discarded, or the next event may be generated.

- Other JSON frameworks (such as JSON binding) is implemented with this API.

Consuming JSON Using the Streaming API

- **JsonParser** contains methods to parse JSON data using the streaming model.

- Json Parser provides forward, read-only access to JSON data using the pull parsing programming model.

- In this model, the application code controls the thread and calls methods in the parser interface to move the parser forward or to obtain JSON data from the current state of the parser.

JSON APIs

- The Java API for JSON Processing contains the following packages:

  - The **javax.json** package contains
    - a reader interface,
    - a writer interface, and
    - a model builder interface for the object model.
      This package also contains other utility classes and Java types for JSON elements.
  - The **javax.json.stream** package contains
    - a parser interface and
    - a generator interface for the streaming model.

JSON-P

Object Model API

Object Model API

- The Object Model API is a high-level API that provides immutable object models for JSON object and array structures.

- These JSON structures are represented as object models via the Java types **JsonObject** and **JsonArray**.

- **JsonObject** provides a Map view to access the unordered collection of zero or more name/value pairs from the model.

- Similarly, **JsonArray** provides a List view to access the ordered sequence of zero or more values from the model.

Object Model API

Consuming JSON Using the Object Model API

- Interfaces you will deal with are:

  - JsonReader

  - JsonStructure

    - JsonObject

    - JsonArray

Consuming JSON Using the Object Model API

- **JsonReader** contains methods to read JSON data using the object model from an input source.

- **JsonReader** can be created from InputStream:
- This code shows how to create a new reader from an InputStream obtained from a new FileInputStream.

```
JsonReader reader = Json.createReader(new FileInputStream(...));
```

- **JsonReader** can also be created from Reader:
- This code shows how to create a reader from a FileReader.

```
JsonReader reader = Json.createReader(new FileReader(...));
```

Consuming JSON Using the Object Model API

- First step to consume JSON using object model is to create a reader object.

- Reader object can be created using
  - FileInputStream object to the JSON file

```
JsonReader reader = Json.createReader(new
FileInputStream(...));
```

  - FileReader object to that contains the JSON data to be consumed.

```
JsonReader reader = Json.createReader(new
FileReader(...));
```

Example Using StringReader "{ " +

- An object with two name/value pairs can be read as:

```
jsonReader = Json.createReader(new StringReader("{"
        + " \"apple\":\"red\","
        + " \"banana\":\"yellow\""
        + "}"));

JsonObject json = jsonReader.readObject();
json.getString("apple");
json.getString("banana");
```

{

apple:"red",

"banana":"yellow"

}

- In this code,
the getString method returns the string value for the specific key in the object.

- Other **_getXXX()_** methods can be used to access the value based upon the data type.

Example

- An array with two objects with each object with a name/value pair can be read as:

```java
jsonReader = Json.createReader(new StringReader("["
        + " { \"apple\":\"red\" },"
        + " { \"banana\":\"yellow\" }"
        + "]"));

JsonArray jsonArray = jsonReader.readArray();
```

```
[
{apple:"red"},
{"banana":"yellow"}
]
```

- In this code, calling the readArray method returns an instance of the **JsonArray** interface. This interface has convenience methods to get boolean, integer, and String values at a specific index.

- This interface extends from **java.util.List**, so usually the list operations are available as well.

Example

- A nested structure can be read as:

```
jsonReader = Json.createReader(new
FileReader("film.json"));

JsonObject movieJsonObject =(JsonObject)
jsonReader.read();
JsonArray cast =
movieJsonObject.getJsonArray("cast");
```

film.json

```
{
    "title":"The Matrix",

    "year":1999,

    "cast":[

        "Keanu Reeves",

        " Laurence Fishburne",

        " Carrie-Anne Moss"]

}
```

Producing JSON Using the Object Model API

- Interfaces you will deal with are:

    - JsonObjectBuilder

    - JsonArrayBuilder

Producing JSON Using the Object Model API

- **JsonObjectBuilder** can be used to create models that represent JSON objects.
- The resulting model is of type JsonObject.

```
JsonObjectBuilder objectBuilder =
factory.createObjectBuilder();
```
- Similarly, **JsonArrayBuilder** can be used to create models that represent JSON arrays where the resulting model is of type **JsonArray**:

```
JsonArrayBuilder objectBuilder =
factory.createArraytBuilder();
```

Example

```
JsonObject model = Json.createObjectBuilder()
 .add("firstName","Duke")
 .add("lastName","Java")
 .add("age", 18)
 .add("city", "JavaTown")
 .add("phoneNumbers", Json.createArrayBuilder()
     .add(Json.createObjectBuilder()
         .add("type", "mobile")
         .add("number", "111-111-1111"))
     .add(Json.createObjectBuilder()
         .add("type", "home")
         .add("number", "222-222-2222")))
.build();
```

```
{
    "firstName": " Duke",
    "lastName": " Java",
    "age":18,
    "city": "JavaTown",
    "phoneNumbers": [
        {"type": "mobile",
        "number": "111-111-1111"},
        {"type": "home",
        "number": "222-222-2222"}
    ]
}
```

Creating a JsonWriter

- The generated JsonObject can be written to an output stream via **JsonWriter**:

```
JsonWriter writer = Json.createWriter(System.out);

writer.writeObject(jsonObject);

writer.writeArray(jsonArray);
```

- In this code, a new **JsonWriter** instance is created and configured to write to **System.out**.

- The previously created **jsonObject and jsonArray** is then written when the **writeObject() and writeArray()** methods are called.

- **JsonWriter** may be configured to write to a Writer as well.

DEMO

- Consuming JSON (Using Object Model API - *JsonReader*)
  - Write a Simple JSON Document
  - Create a JSON Reader, to read JSON object/array from that Document
  - Use *getXXX()* methods to retrieve data from those objects

- Producing JSON (Using Object Model API – *JsonWriter*)
  - Create a Json Writer
  - Create a JSON Structure (Object/Array) using Builders
  - Write out those JSON Structures
  - Write the JSON Contents to a File by flushing/closing the generator

JSON-B

Introduction

What is JSON-B?

    JSON-B is a standard binding layer for converting
Java objects to/from JSON messages.

It defines a default mapping algorithm for converting existing Java classes to JSON, while enabling developers to customize the mapping process through the use of Java annotations.

Java API for JSON Binding

    JEE8: JSR 367 Specification

Mapping an Object

- The main JSON-B entry point is **Jsonb** class.

- It provides all necessary methods to serialize and deserialize Java objects.

- Jsonb instances are thread safe. They can be cached and reused.

```java
public class Dog { public String name; public int age; public boolean bitable; }

// Create a dog instance
Dog dog = new Dog();
dog.name = "Falco";
dog.age = 4;
dog.bitable = false;

// Create Jsonb and serialize
Jsonb jsonb = JsonbBuilder.create();
String result = jsonb.toJson(dog);

// Deserialize back
dog = jsonb.fromJson("{\"age\":4,\"bitable\":false,\"name\":\"Falco\"}", Dog.class);
```

Mapping a raw Collection

- JSON-B supports native arrays serialization.

```java
// List of dogs
Dog[] dogs = new Dog[] {
    new Dog( ... ),
    new Dog( ... )
};

// Create Jsonb and serialize
Jsonb jsonb = JsonbBuilder.create();
String result = jsonb.toJson(dogs);

// We can also deserialize back into a raw collection,
dogs = jsonb.fromJson(result, Dog[].class);
```

Mapping a Generic Collection

- JSON-B supports raw collections serialization.

```java
// List of dogs
List list = new ArrayList();
list.add(falco);
list.add(cassidy);

// Create Jsonb and serialize
Jsonb jsonb = JsonbBuilder.create();
String result = jsonb.toJson(dogs);

// We can also deserialize back into a raw collection,
// but since there is no way to infer a type here,
// the result will be a list of java.util.Map instances with string keys.
dogs = jsonb.fromJson(result, new ArrayList().getClass());
```

Demo

- ***Default Mapping of JSON-B***
  - Mapping an object
  - Mapping a raw collection
  - Mapping a generic collection

Appendix

Gson

Google Gson

- Google Gson is an open source,
  Java-based library developed by Google.

- It facilitates serialization of Java objects to JSON and vice versa.

- This tutorial adopts a simple and intuitive way to describe the
  basic-to-advanced concepts of Google Gson and how to use its APIs.

- Available at : github.com/google/gson

Example

- Before going into the details of the Google Gson library,
  let's see an application in action.

- In this example, we've created a **Student class**.

- We'll create a JSON string with student details and deserialize it to student object and then serialize it to an JSON String.

Student Class

```java
public class Student {

    private String name;
    private int age;

    public Student(){ }

    public String getName() { return name; }

    public void setName(String name) { this.name = name; }

    public int getAge() { return age; }

    public void setAge(int age) { this.age = age; }

    public String toString() {
        return "Student [ name: "+name+", age: "+ age+ " ]";
    }

}
```

Steps to Remember

- **Step 1 –** *Create Gson object using GsonBuilder*

```
GsonBuilder builder = new GsonBuilder();
builder.setPrettyPrinting();
Gson gson = builder.create();
```

- **Step 2 –** *Deserialize JSON to Object*

```
//Object to JSON Conversion
Student student = gson.fromJson(jsonString, Student.class);
```

- **Step 3 –** *Serialize Object to JSON*

```
//Object to JSON Conversion
jsonString = gson.toJson(student);
```

Tester Class

```java
public class GsonTester {

    public static void main(String[] args) {
        String jsonString = "{\"name\":\"Ahmed Aboulroos\", \"age\":25}";

        GsonBuilder builder = new GsonBuilder();
        builder.setPrettyPrinting();

        Gson gson = builder.create();
        Student student = gson.fromJson(jsonString, Student.class);
        System.out.println(student);

        jsonString = gson.toJson(studer
        System.out.println(jsonString)
    }
}
```

Student [name: Ahmed Aboulroos, age: 25]

{
  "name": "Ahmed Aboulroos",
  "age": 25
}

Gson Class

- Gson is the main actor class of Google Gson library.

- It provides functionalities to convert Java objects to matching JSON constructs and vice versa.

- Gson is first constructed using GsonBuilder and then,
  toJson(Object) or fromJson(String, Class) methods
  are used to read/write JSON constructs.

- Java Doc API for Gson
  - https://www.javadoc.io/doc/com.google.code.gson/gson/latest/com.google.gson/com/google/gson/Gson.html

Gson - Object Serialization

- Let's serialize a Java object to a Json file
  and then read that Json file to get the object back.

- In this example, we've created a Student class.

- We'll generate a **student.json** file which will have
  a json representation of Student object.

GsonTester Class

```java
public static void main(String[] args) {
    GsonTester tester = new GsonTester();
    try {
        Student student = new Student();
        student.setAge(25);
        student.setName("Ahmed Ali");
        tester.writeJSON(student);
        Student student1 = tester.readJSON();
        System.out.println(student1);
    } catch (IOException e) {
        e.printStackTrace();
    }
}
```

GsonTester Class

```java
private void writeJSON(Student student) throws IOException {
    GsonBuilder builder = new GsonBuilder();
    builder.setPrettyPrinting();
    Gson gson = builder.create();
    FileWriter writer = new FileWriter("student.json");
    writer.write(gson.toJson(student));
    writer.close();
}
```

```java
private Student readJSON() throws FileNotFoundException {
    GsonBuilder builder = new GsonBuilder();
    Gson gson = builder.create();
    BufferedReader bufferedReader = new BufferedReader(new
FileReader("student.json"));

    Student student = gson.fromJson(bufferedReader, Student.class);
    return student;
}
```
