

Difference between **Constructor Function** Vs **Object Literal**?

JS

Constructor function is used to create new objects with properties and methods. It is called with the **new** keyword and can take arguments to set the values of object properties.

```
// using constructor function
function Person() {
  this.name = 'Andrew'
}

let person1 = new Person();
let person2 = new Person();
console.log('person1', person1) // Person { name: 'Andrew' }
console.log('person2', person2) // Person { name: 'Andrew' }
```

Object literal is a way to create a new object by listing its properties and values in curly braces {}. It does **not** have a constructor function or methods.

```
// using object literal
let person = {
  name: 'Andrew',
}

const { name } = person
console.log(name) // Output: Andrew
```

Object Literal is generally used to create a single object. The **constructor function** is useful if you want to create multiple objects.

Each object created from the **constructor function** is unique. You can have the same properties as the constructor function or add a new property to one particular object.

```
function Person() {  
  this.name = 'Adrew'  
}  
let person1 = new Person();  
let person2 = new Person();  
// adding new property to person1  
person1.age = 22;  
person2.country = 'USA'  
console.log('person1', person1); //Output: Person { name: 'Adrew', age: 22 }  
console.log('person2', person2); //Output: Person { name: 'Adrew', country: 'USA' }
```

age property is unique to **person1** object and is not available to **person2** object. Same for **country** property.

If an **object** is created with an **object literal**, and if a variable is defined with that object value, any **changes** in variable value will change the **original** object.

```
let person = {  
  name: 'Andrew'  
}  
console.log(person.name); // Andrew  
let student = person;  
// Assigns new object to student  
student.name = 'John';  
// Original object is also updated  
console.log(person.name); // John
```
